

Prawn

by example

Last Update: 2016-02-29 Prawn Version: 2.1.0 git commit: ff27f7e

How to read this manual

This manual is a collection of examples categorized by theme and organized from the least to the most complex. While it covers most of the common use cases it is not a comprehensive guide.

The best way to read it depends on your previous knowledge of Prawn and what you need to accomplish.

If you are beginning with Prawn the first chapter will teach you the most basic concepts and how to create pdf documents. For an overview of the other features each chapter beyond the first either has a Basics section (which offer enough insight on the feature without showing all the advanced stuff you might never use) or is simple enough with only a few examples.

Once you understand the basics you might want to come back to this manual looking for examples that accomplish tasks you need.

Advanced users are encouraged to go beyond this manual and read the source code directly if any doubt is not directly covered on this manual.

Reading the examples

The title of each example is the relative path from the Prawn source manual/folder.

The first body of text is the introductory text for the example. Generally it is a short description of the features illustrated by the example.

Next comes the example source code block in fixed width font.

Most of the example snippets illustrate features that alter the page in place. The effect of these snippets is shown right below a dashed line. If it doesn't make sense to evaluate the snippet inline, a box with the link for the example file is shown instead.

Note that the stroke_axis method used throughout the manual is part of standard Prawn. It is defined in this file:

https://github.com/prawnpdf/prawn/blob/master/lib/prawn/graphics.rb

Basic concepts

This chapter covers the minimum amount of functionality you'll need to start using Prawn.

If you are new to Prawn this is the first chapter to read. Once you are comfortable with the concepts shown here you might want to check the Basics section of the Graphics, Bounding Box and Text sections.

The examples show:

- · How to create new pdf documents in every possible way
- Where the origin for the document coordinates is. What are Bounding Boxes and how they interact with the origin
- · How the cursor behaves
- · How to start new pages
- What the base unit for measurement and coordinates is and how to use other convenient measures
- · How to build custom view objects that use Prawn's DSL

basic concepts/creation.rb

There are three ways to create a PDF Document in Prawn: creating a new Prawn::Document instance, or using the Prawn::Document.generate method with and without block arguments.

The following snippet showcase each way by creating a simple document with some text drawn.

When we instantiate the **Prawn::Document** object the actual pdf document will only be created after we call **render file**.

The generate method will render the actual pdf object after exiting the block. When we use it without a block argument the provided block is evaluated in the context of a newly created <code>Prawn::Document</code> instance. When we use it with a block argument a <code>Prawn::Document</code> instance is created and passed to the block.

The generate method without block arguments requires less typing and defines and renders the pdf document in one shot. Almost all of the examples are coded this way.

Assignment Implicit Block Explicit Block

```
# Assignment
pdf = Prawn::Document.new
pdf.text "Hello World"
pdf.render_file "assignment.pdf"

# Implicit Block
Prawn::Document.generate("implicit.pdf") do
    text "Hello World"
end

# Explicit Block
Prawn::Document.generate("explicit.pdf") do |pdf|
    pdf.text "Hello World"
end
```

This code snippet was not evaluated inline. You may see its output by running the example file located here: http://github.com/prawnpdf/prawn/tree/master/manual/basic_concepts/creation.rb

basic_concepts/origin.rb

This is the most important concept you need to learn about Prawn:

PDF documents have the origin [0,0] at the bottom-left corner of the page.

A bounding box is a structure which provides boundaries for inserting content. A bounding box also has the property of relocating the origin to its relative bottom-left corner. However, be aware that the location specified when creating a bounding box is its top-left corner, not bottom-left (hence the [100, 300] coordinates below).

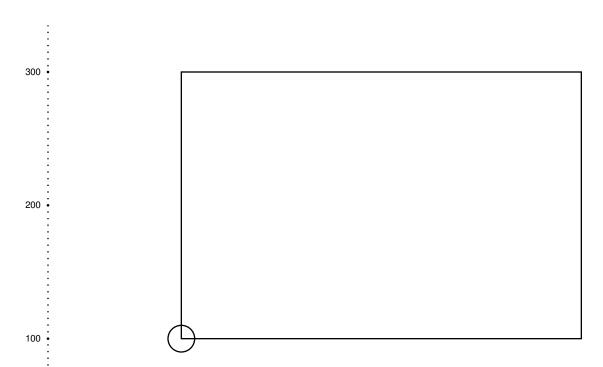

Even if you never create a bounding box explictly, each document already comes with one called the margin box. This initial bounding box is the one responsible for the document margins.

So practically speaking the origin of a page on a default generated document isn't the absolute bottom left corner but the bottom left corner of the margin box.

The following snippet strokes a circle on the margin box origin. Then strokes the boundaries of a bounding box and a circle on its origin.

```
stroke_axis
stroke_circle [0, 0], 10

bounding_box([100, 300], :width => 300, :height => 200) do
    stroke_bounds
    stroke_circle [0, 0], 10
end
```

100 200 300 400 500

basic_concepts/cursor.rb

We normally write our documents from top to bottom and it is no different with Prawn. Even if the origin is on the bottom left corner we still fill the page from the top to the bottom. In other words the cursor for inserting content starts on the top of the page.

Most of the functions that insert content on the page will start at the current cursor position and proceed to the bottom of the page.

The following snippet shows how the cursor behaves when we add some text to the page and demonstrates some of the helpers to manage the cursor position. The **cursor** method returns the current cursor position.

```
text "the cursor is here: #{cursor}"
text "now it is here: #{cursor}"

move_down 200
text "on the first move the cursor went down to: #{cursor}"

move_up 100
text "on the second move the cursor went up to: #{cursor}"

move_cursor_to 50
text "on the last move the cursor went directly to: #{cursor}"
```

the cursor is here: 383.9795

300

200

100

now it is here: 370.1074999999996

on the second move the cursor went up to: 242.36349999999993

on the first move the cursor went down to: 156.23549999999994

on the last move the cursor went directly to: 50.0

100 200 300 400 500

basic_concepts/other_cursor_helpers.rb

Another group of helpers for changing the cursor position are the pad methods. They accept a numeric value and a block. pad will use the numeric value to move the cursor down both before and after the block content. pad_top will only move the cursor before the block while pad_bottom will only move after.

float is a method for not changing the cursor. Pass it a block and the cursor will remain on the same place when the block returns.

```
stroke_horizontal_rule
pad(20) { text "Text padded both before and after." }

stroke_horizontal_rule
pad_top(20) { text "Text padded on the top." }

stroke_horizontal_rule
pad_bottom(20) { text "Text padded on the bottom." }

stroke_horizontal_rule
move_down 30

text "Text written before the float block."

float do
   move_down 30
   bounding_box([0, cursor], :width => 200) do
        text "Text written inside the float block."
        stroke_bounds
   end
end

text "Text written after the float block."
```

Text padded both before and after.

Text padded on the top.

Text padded on the bottom.

Text written before the float block. Text written after the float block.

Text written inside the float block.

basic_concepts/adding_pages.rb

A PDF document is a collection of pages. When we create a new document be it with **Document.new** or on a **Document.generate** block one initial page is created for us.

Some methods might create new pages automatically likeext which will create a new page whenever the text string cannot fit on the current page.

But what if you want to go to the next page by yourself? That is easy.

Just use the start_new_page method and a shiny new page will be created for you just like in the following snippet.

```
text "We are still on the initial page for this example. Now I'll ask " +
    "Prawn to gently start a new page. Please follow me to the next page."

start_new_page

text "See. We've left the previous page behind."
```

We are still on the initial page for this example. Now I'll ask Prawn to gently start a new page. Please follow me to the next page.

basic_concepts/measurement.rb

The base unit in Prawn is the PDF Point. One PDF Point is equal to 1/72 of an inch.

There is no need to waste time converting this measure. Prawn provides helpers for converting from other measurements to PDF Points.

Just require "prawn/measurement_extensions" and it will mix some helpers onto Numeric for converting common measurement units to PDF Points.

```
require "prawn/measurement_extensions"

[:mm, :cm, :dm, :m, :in, :yd, :ft].each do |measurement|
  text "1 #{measurement} in PDF Points: #{1.send(measurement)} pt"
  move_down 5.mm
end
```

1 mm in PDF Points: 2.834645669291339 pt

1 cm in PDF Points: 28.34645669291339 pt

1 dm in PDF Points: 283.46456692913387 pt

1 m in PDF Points: 2834.645669291339 pt

1 in in PDF Points: 72 pt

1 yd in PDF Points: 2592 pt

1 ft in PDF Points: 864 pt

basic_concepts/view.rb

To create a custom class that extends Prawn's functionality, use theawn::view mixin. This approach is safer than creating subclasses of Prawn::Document while being just as convenient.

By using this mixin, your state will be kept completely separate from Prawn::Document's state, and you will avoid accidental method collisions within Prawn::Document.

To build custom classes that make use of other custom classes, you can define a method named document() that returns any object that acts similar to a Prawn::Document object. Prawn::View will then direct all delegated calls to that object instead.

```
class Greeter
  include Prawn::View

def initialize(name)
    @name = name
  end

def say_hello
    text "Hello, #{@name}!"
  end

def say_goodbye
    font("Courier") do
        text "Goodbye, #{@name}!"
    end
  end
end

greeter = Greeter.new("Gregory")

greeter.say_hello
  greeter.say_goodbye

greeter.save_as("greetings.pdf")
```

This code snippet was not evaluated inline. You may see its output by running the example file located here: http://github.com/prawnpdf/prawn/tree/master/manual/basic_concepts/view.rb

Graphics

Here we show all the drawing methods provided by Prawn. Use them to draw the most beautiful imaginable things.

Most of the content that you'll add to your pdf document will use the graphics package. Even text is rendered on a page just like a rectangle so even if you never use any of the shapes described here you should at least read the basic examples.

The examples show:

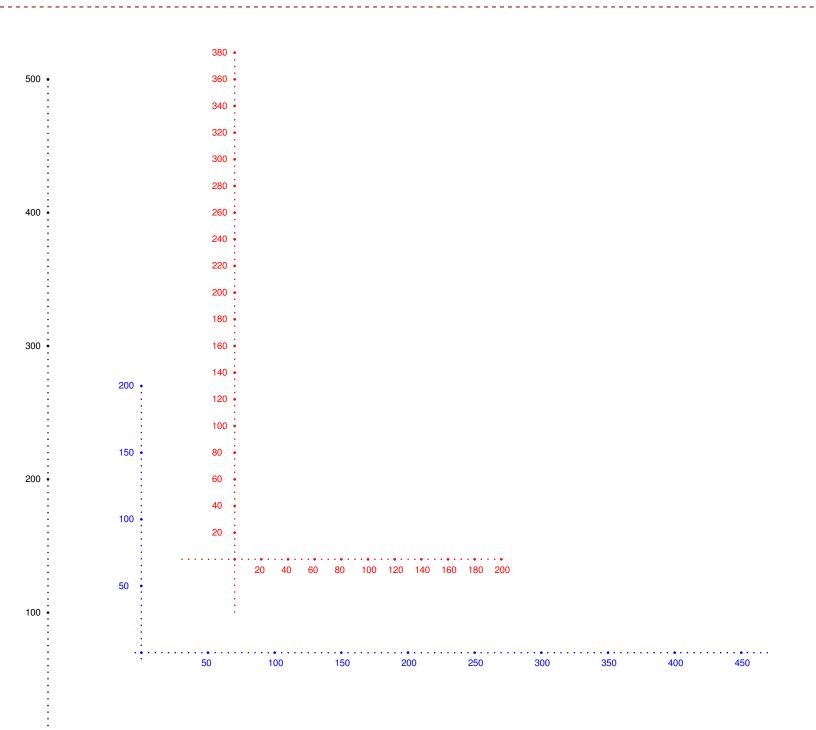

- All the possible ways that you can fill or stroke shapes on a page
- How to draw all the shapes that Prawn has to offer from a measly line to a mighty polygon or ellipse
- The configuration options for stroking lines and filling shapes
- · How to apply transformations to your drawing space

graphics/helper.rb

To produce this manual we use the stroke_axis helper method within the examples.

stroke_axis prints the x and y axis for the current bounding box with markers in 100 increments. The defaults can be changed with various options.

Note that the examples define a custom :height option so that only the example canvas is used (as seen with the output of the first line of the example code).

graphics/fill_and_stroke.rb

There are two drawing primitives in Prawn: fill and stroke.

These are the methods that actually draw stuff on the document. All the other drawing shapes like rectangle, circle or line_to define drawing paths. These paths need to be either stroked or filled to gain form on the document.

Calling these methods without a block will act on the drawing path that has been defined prior to the call.

Calling with a block will act on the drawing path set within the block.

Most of the methods which define drawing paths have methods of the same name starting with stroke_ and fill_ which create the drawing path and then stroke or fill it.

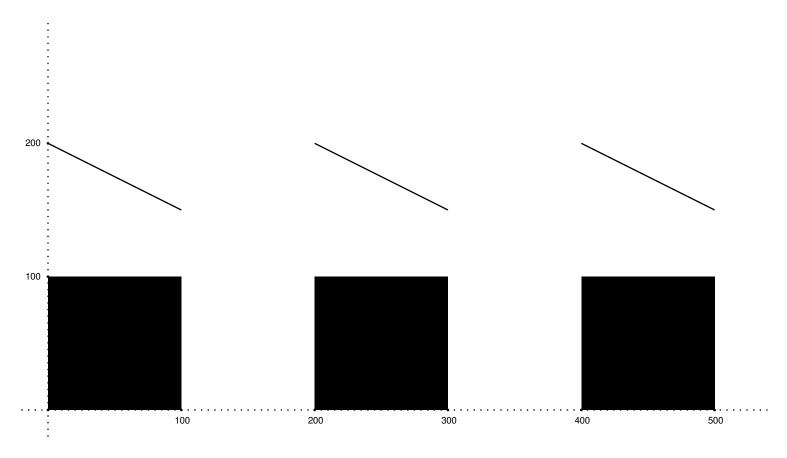

```
stroke_axis

# No block
line [0, 200], [100, 150]
stroke

rectangle [0, 100], 100, 100
fill

# With block
stroke { line [200, 200], [300, 150] }
fill { rectangle [200, 100], 100, 100 }

# Method hook
stroke_line [400, 200], [500, 150]
fill_rectangle [400, 100], 100, 100
```

graphics/lines_and_curves.rb

Prawn supports drawing both lines and curves starting either at the current position, or from a specified starting position.

line_to and curve_to set the drawing path from the current drawing position to the specified point. The initial drawing position can be set withove_to. They are useful when you want to chain successive calls because the drawing position will be set to the specified point afterwards.

line and curve set the drawing path between the two specified points.

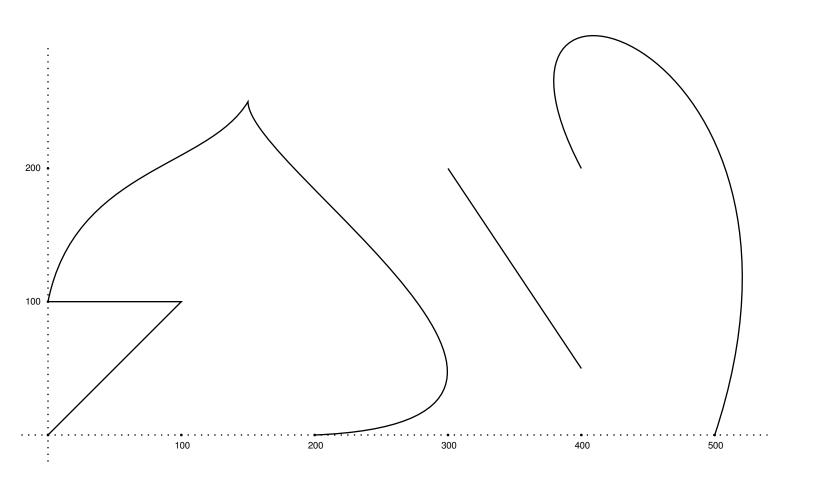

Both curve methods define a Bezier curve bounded by two aditional points provided as the :bounds param.

```
stroke_axis
# line_to and curve_to
stroke do
    move_to 0, 0

line_to 100, 100
line_to 0, 100

curve_to [150, 250], :bounds => [[20, 200], [120, 200]]
    curve_to [200, 0], :bounds => [[150, 200], [450, 10]]
end

# line and curve
stroke do
    line [300, 200], [400, 50]
    curve [500, 0], [400, 200], :bounds => [[600, 300], [300, 390]]
end
```

graphics/common_lines.rb

Prawn provides helpers for drawing some commonly used lines:

vertical_line and horizontal_line do just what their names imply. Specify the start and end point at a fixed coordinate to define the line.

horizontal_rule draws a horizontal line on the current bounding box from border to border, using the current y position.

```
stroke_axis
stroke_color "ff0000"

stroke do
    # just lower the current y position
    move_down 50
    horizontal_rule

vertical_line 100, 300, :at => 50

horizontal_line 200, 500, :at => 150
end
```

```
200
```

100 200 300 400 50

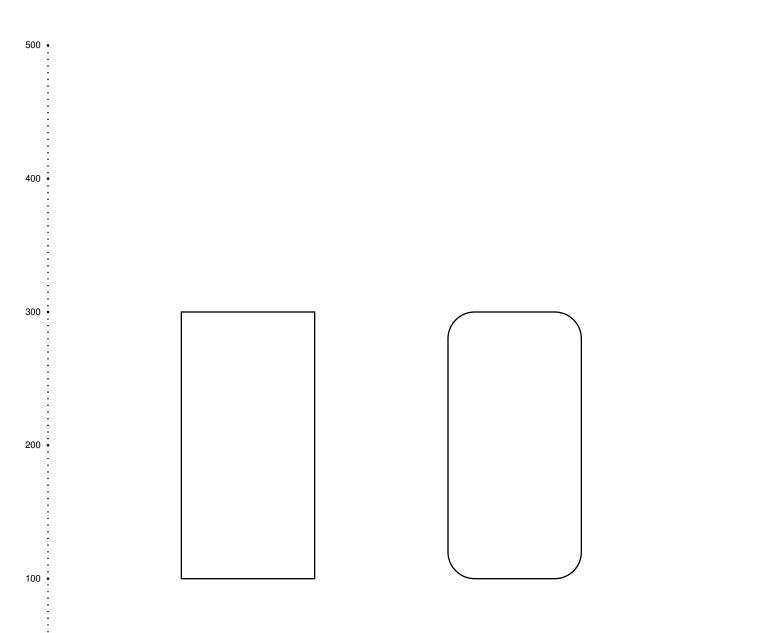

graphics/rectangle.rb

To draw a rectangle, just provide the upper-left corner, width and height to therectangle method.

There's also **rounded_rectangle**. Just provide an additional radius value for the rounded corners.

```
stroke_axis
stroke do
  rectangle [100, 300], 100, 200

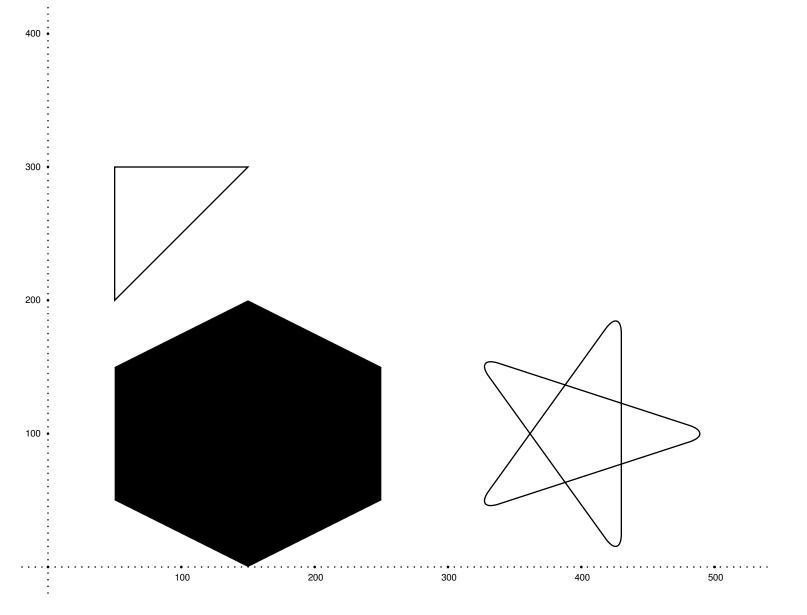

rounded_rectangle [300, 300], 100, 200, 20
end
```

graphics/polygon.rb

Drawing polygons in Prawn is easy, just pass a sequence of points to one of the polygon family of methods.

Just like rounded_rectangle we also have rounded_polygon. The only difference is the radius param comes before the polygon points.

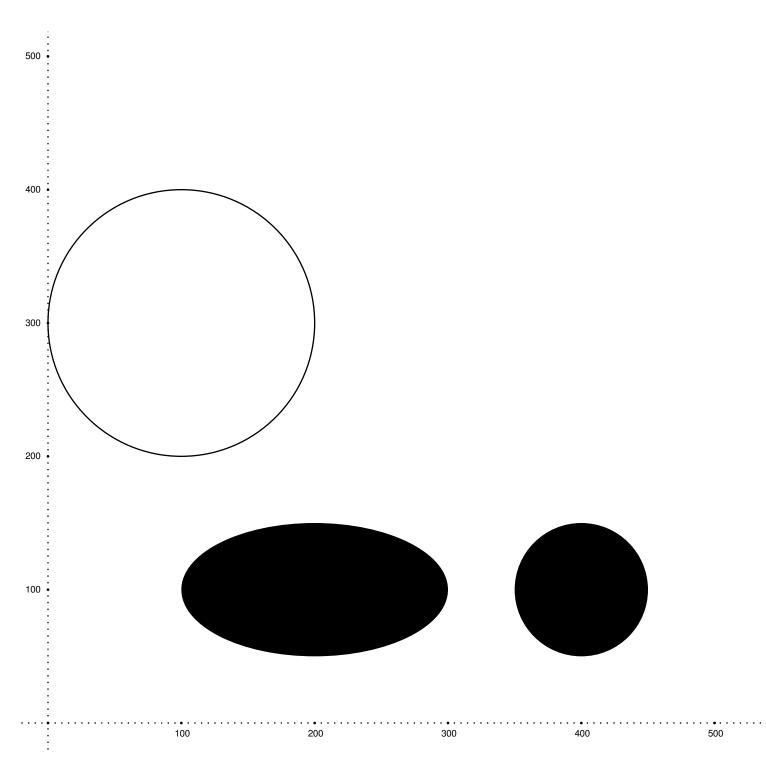

graphics/circle_and_ellipse.rb

To define a circle all you need is the center point and the radius.

To define an ellipse you provide the center point and two radii (or axes) values. If the second radius value is ommitted, both radii will be equal and you will end up drawing a circle.

```
stroke_axis
stroke_circle [100, 300], 100
fill_ellipse [200, 100], 100, 50
fill_ellipse [400, 100], 50
```

graphics/line_width.rb

The line_width= method sets the stroke width for subsequent stroke calls.

Since Ruby assumes that an unknown variable on the left hand side of an assignment is a local temporary, rather than a setter method, if you are using the block call to <code>Prawn::Document.generate</code> Without passing params you will need to calline_width on self

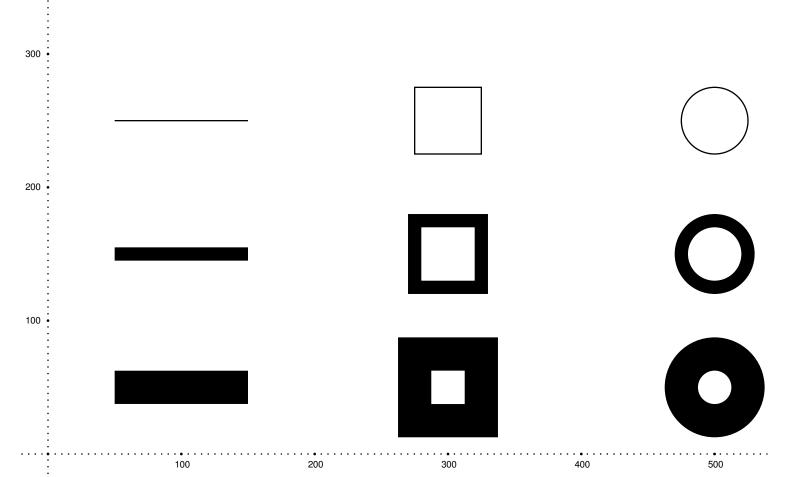

```
stroke_axis

y = 250

3.times do |i|
   case i
   when 0 then line_width = 10  # This call will have no effect
   when 1 then self.line_width = 10
   when 2 then self.line_width = 25
   end

stroke do
   horizontal_line 50, 150, :at => y
   rectangle [275, y + 25], 50, 50
   circle [500, y], 25
   end

y -= 100
end
```

graphics/stroke_cap.rb

The cap style defines how the edge of a line or curve will be drawn. There are three types: :butt (the default), :round and :projecting_square

The difference is better seen with thicker lines. With :butt lines are drawn starting and ending at the exact points provided. With both:round and :projecting_square the line is projected beyond the start and end points.

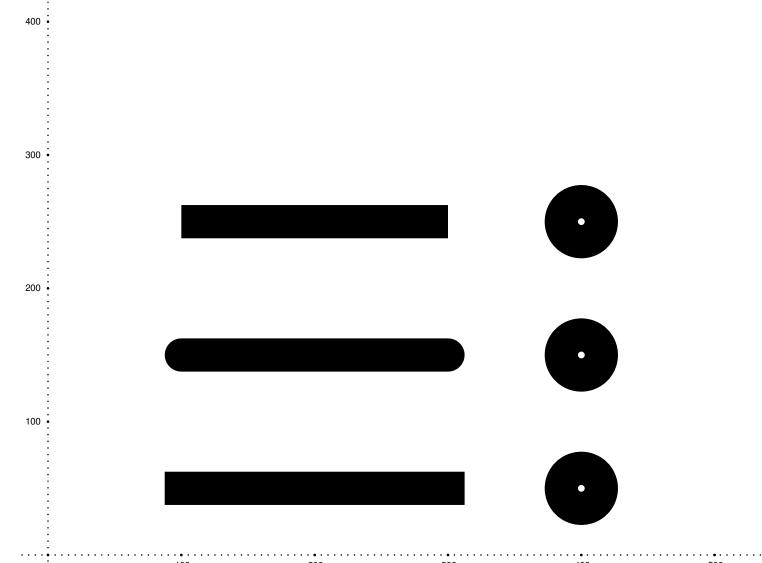

Just like line_width= the cap_style= method needs an explicit receiver to work.

```
stroke_axis

self.line_width = 25

[:butt, :round, :projecting_square].each_with_index do |cap, i|
    self.cap_style = cap

y = 250 - i * 100
    stroke_horizontal_line 100, 300, :at => y
    stroke_circle [400, y], 15
end
```

graphics/stroke_join.rb

400 :

The join style defines how the intersection between two lines is drawn. There are three types: :miter(the default), :round and :bevel

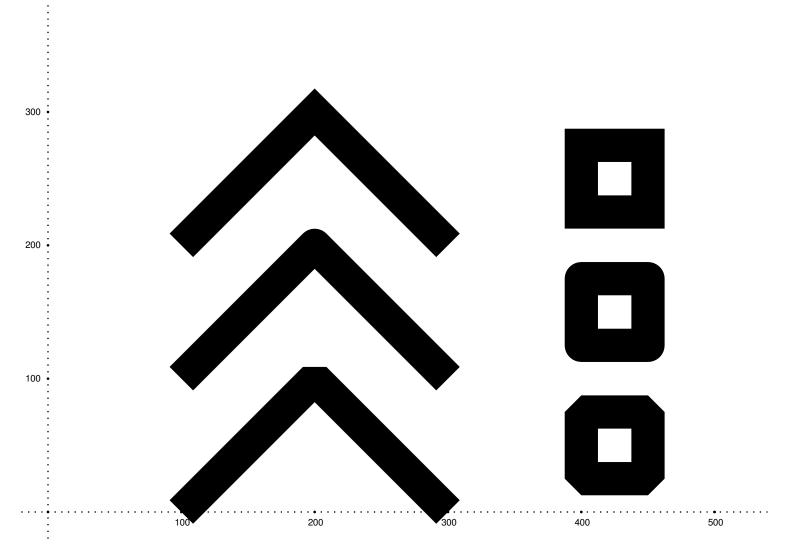

Just like cap_style, the difference between styles is better seen with thicker lines.

```
stroke_axis

self.line_width = 25

[:miter, :round, :bevel].each_with_index do |style, i|
    self.join_style = style

y = 200 - i * 100
    stroke do
    move_to(100, y)
    line_to(200, y + 100)
    line_to(300, y)
    end
    stroke_rectangle [400, y + 75], 50, 50
end
```

graphics/stroke_dash.rb

200 •

100

This sets the dashed pattern for lines and curves. The (dash) length defines how long each dash will be.

The :space option defines the length of the space between the dashes.

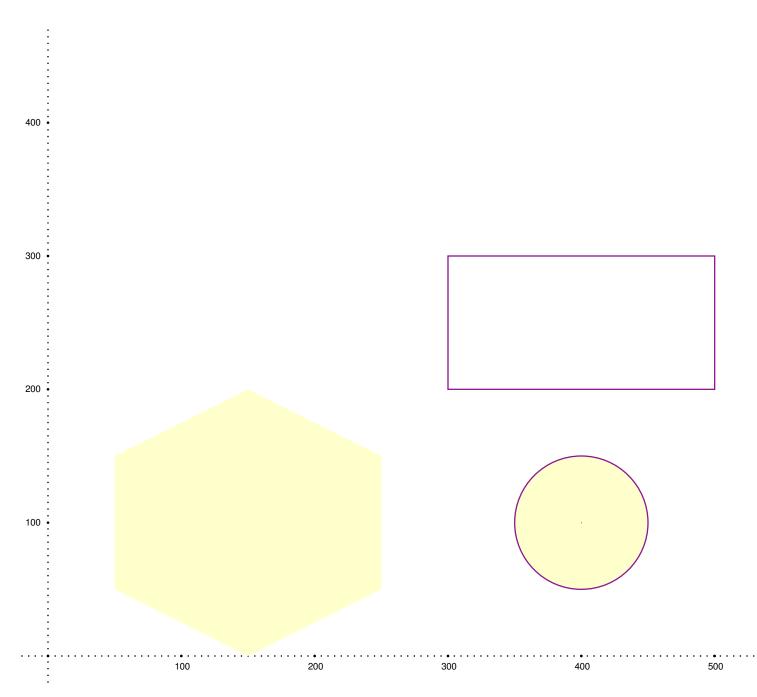

The :phase option defines the start point of the sequence of dashes and spaces.

Complex dash patterns can be specified by using an array with alternating dash/gap lengths for the first parameter (note that the :space option is ignored in this case).

100 200 300 400 50

graphics/color.rb

We can change the stroke and fill colors providing an HTML rgb 6 digit color code string ("AB1234") or 4 values for CMYK.

graphics/gradients.rb

Note that because of the way PDF renders radial gradients in order to get solid fill your start circle must be fully inside your end circle. Otherwise you will get triangle fill like illustrated in the example below.

```
stroke_axis
self.line_width = 10

fill_gradient [50, 300], [150, 200], 'ff0000', '0000ff'
fill_rectangle [50, 300], 100, 100

stroke_gradient [200, 200], [300, 300], '00ffff', 'ffff00'
stroke_rectangle [200, 300], 100, 100

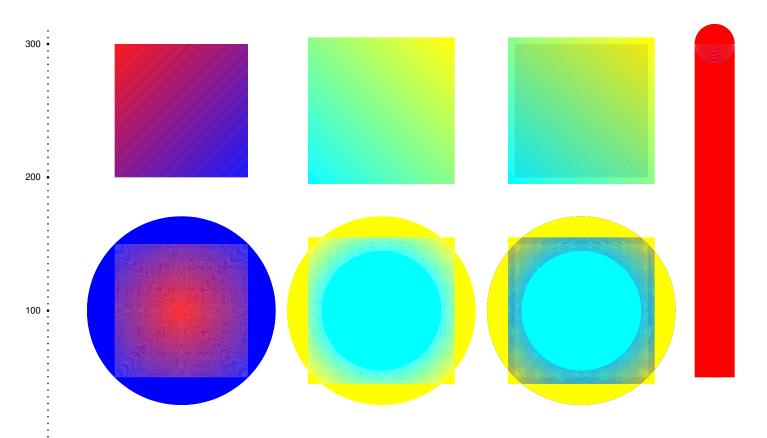

fill_gradient [350, 300], [450, 200], 'ff0000', '0000ff'
stroke_gradient [350, 200], [450, 300], '00ffff', 'ffff00'
fill_and_stroke_rectangle [350, 300], 100, 100

fill_gradient [100, 100], 0, [100, 100], 70.71, 'ff0000', '0000ff'
fill_rectangle [50, 150], 100, 100

stroke_gradient [250, 100], 45, [250, 100], 70.71, '00ffff', 'ffff00'
stroke_rectangle [200, 150], 100, 100

stroke_gradient [400, 100], 0, [400, 100], 70.71, '00ffff', 'ffff00'
fill_gradient [400, 100], 0, [400, 100], 70.71, 'ff0000', '0000ff'
fill_and_stroke_rectangle [350, 150], 100, 100

fill_gradient [500, 300], 15, [500, 50], 0, 'ff0000', '0000ff'
fill_rectangle [485, 300], 30, 250
```

100 200 300 400 5

graphics/transparency.rb

Although the name of the method is transparency, what we are actually setting is the opacity for fill and stroke. So 0 means completely transparent and 1.0 means completely opaque

You may call it providing one or two values. The first value sets fill opacity and the second value sets stroke opacity. If the second value is omitted fill and stroke will have the same opacity.

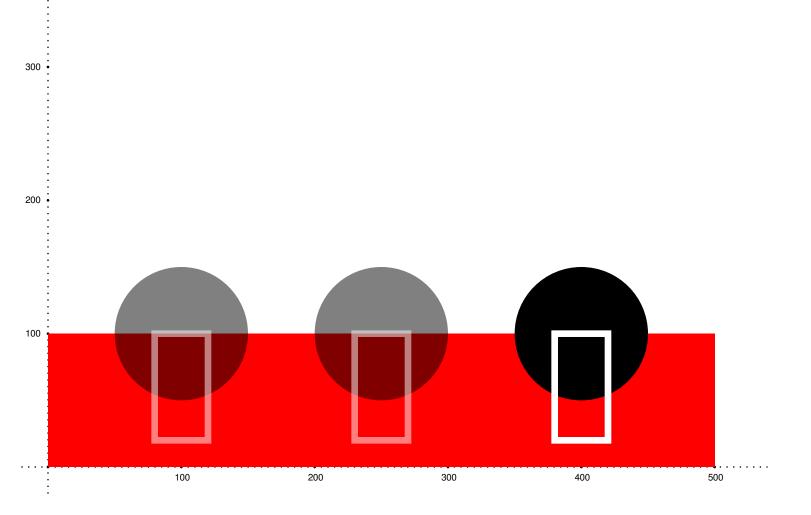

```
stroke_axis

self.line_width = 5
fill_color "ff0000"
fill_rectangle [0, 100], 500, 100

fill_color "0000000"
stroke_color "fffffff"

base_x = 100
[[0.5, 1], 0.5, [1, 0.5]].each do |args|
transparent(*args) do
    fill_circle [base_x, 100], 50
    stroke_rectangle [base_x - 20, 100], 40, 80
end

base_x += 150
end
```

graphics/soft_masks.rb

Soft masks are used for more complex alpha channel manipulations. You can use arbitrary drawing functions for creation of soft masks. The resulting alpha channel is made of greyscale version of the drawing (luminosity channel to be precise). So while you can use any combination of colors for soft masks it's easier to use greyscales. Black will result in full transparency and white will make region fully opaque.

Soft mask is a part of page graphic state. So if you want to apply soft mask only to a part of page you need to enclose drawing instructions in save_graphics_state block.

```
save_graphics_state do
    soft_mask do
    0.upto 15 do |i|
        fill_color 0, 0, 0, 100.0 / 16.0 * (15 - i)
        fill_circle [75 + i * 25, 100], 60
    end
end

fill_color '009ddc'
fill_rectangle [0, 60], 600, 20

fill_color '963d97'
fill_rectangle [0, 80], 600, 20

fill_color 'e03a3e'
fill_rectangle [0, 100], 600, 20

fill_color 'f5821f'
fill_rectangle [0, 120], 600, 20

fill_color 'fdb827'
fill_rectangle [0, 140], 600, 20

fill_color 'fdb827'
fill_rectangle [0, 140], 600, 20

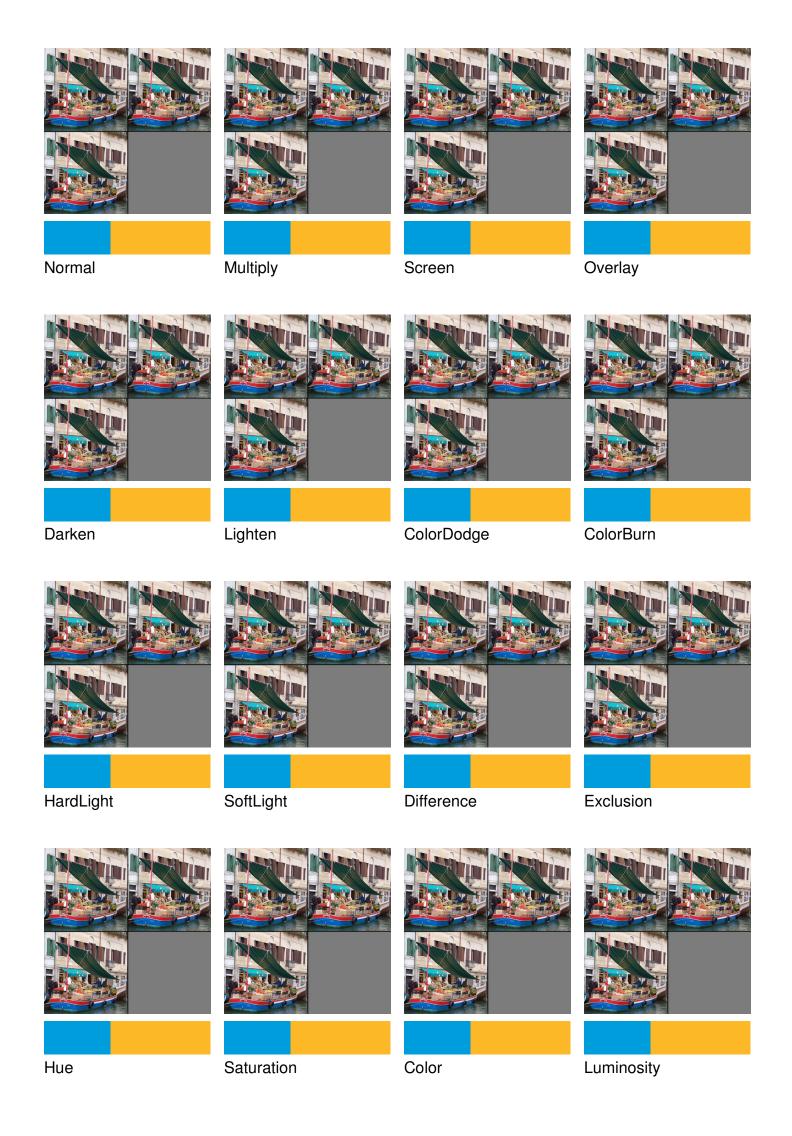

end
```

graphics/blend mode.rb

Blend modes can be used to change the way two layers (images, graphics, text, etc.) are blended together. The blend_mode method accepts a single blend mode or an array of blend modes. PDF viewers should blend the layers based on the first recognized blend mode.

Valid blend modes in v1.4 of the PDF spec include :Normal, :Multiply, :Screen, :Overlay, :Darken, :Lighten, :ColorDodge, :ColorBurn, :HardLight, :SoftLight, :Difference, :Exclusion, :Hue, :Saturation, :Color, and :Luminosity.

```
start_new_page
layer.jpg#/media/File:Blend_modes_2.-bottom-layer.jpg
bottom_layer = "#{Prawn::DATADIR}/images/blend_modes_bottom_layer.jpg"
top_layer = "#{Prawn::DATADIR}/images/blend_modes_top_layer.jpg"
blend_modes = [:Normal, :Multiply, :Screen, :Overlay, :Darken, :Lighten,
 :Saturation, :Color, :Luminosity]
blend_modes.each_with_index do |blend_mode, index|
  x = index % 4 * 135
  image bottom_layer, :at \Rightarrow [x, y], :fit \Rightarrow [125, 125]
  blend_mode(blend_mode) do
    image top_layer, :at => [x, y], :fit => [125, 125]
  fill_rectangle [x, y], 75, 25
  blend_mode(blend_mode) do
    fill_color 'fdb827'
    fill_rectangle [x + 50, y], 75, 25
  fill_color '000000'
  text_box blend_mode.to_s, :at => [x, y]
```

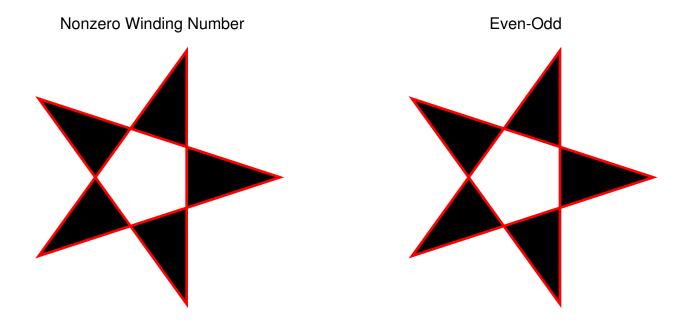

graphics/fill rules.rb

Prawn's fill operators (fill and fill_and_stroke both accept a :fill_rule option. These rules determine which parts of the page are counted as "inside" vs. "outside" the path. There are two fill rules:

- * :nonzero_winding_number (default): a point is inside the path if a ray from that point to infinity crosses a nonzero "net number" of path segments, where path segments intersecting in one direction are counted as positive and those in the other direction negative.
- * :even_odd: A point is inside the path if a ray from that point to infinity crosses an odd number of path segments, regardless of direction.

The differences between the fill rules only come into play with complex paths; they are identical for simple shapes.

graphics/rotate.rb

This transformation is used to rotate the user space. Give it an angle and an :origin point about which to rotate and a block. Everything inside the block will be drawn with the rotated coordinates.

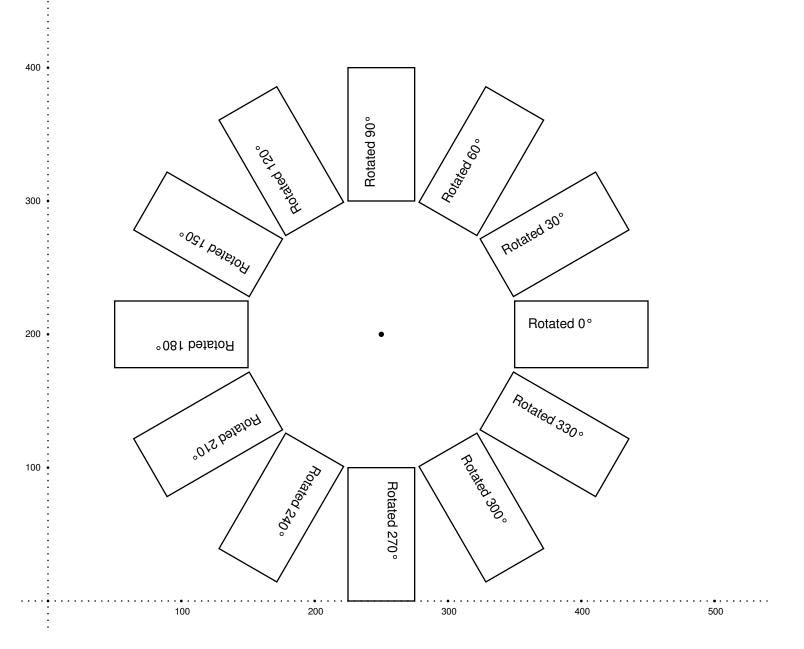

The angle is in degrees.

If you omit the :origin option the page origin will be used.

```
stroke_axis

fill_circle [250, 200], 2

12.times do |i|
  rotate(i * 30, :origin => [250, 200]) do
    stroke_rectangle [350, 225], 100, 50
    draw_text "Rotated #{i * 30}°", :size => 10, :at => [360, 205]
  end
end
```

graphics/translate.rb

This transformation is used to translate the user space. Just provide the x and y coordinates for the new origin.

Top left corner at [100,75]

400 :

300

200

100

• New origin after translation to [150, 300]

Top left corner at [100,75]

• New origin after translation to [100, 200]

Top left corner at [100,75]

• New origin after translation to [50, 100]

00 200 300 400 500

graphics/scale.rb

This transformation is used to scale the user space. Give it an scale factor and an :origin point and everything inside the block will be scaled using the origin point as reference.

If you omit the :origin option the page origin will be used.

200

100

reference rectangle

rectangle scaled from upper-left corner

rectangle scaled from center

Text

This is probably the feature people will use the most. There is no shortage of options when it comes to text. You'll be hard pressed to find a use case that is not covered by one of the text methods and configurable options.

The examples show:

- Text that flows from page to page automatically starting new pages when necessary
- · How to use text boxes and place them on specific positions
- · What to do when a text box is too small to fit its content
- Flowing text in columns
- · How to change the text style configuring font, size, alignment and many other settings
- · How to style specific portions of a text with inline styling and formatted text
- · How to define formatted callbacks to reuse common styling definitions
- · How to use the different rendering modes available for the text methods
- · How to create your custom text box extensions
- · How to use external fonts on your pdfs
- · What happens when rendering text in different languages

text/free flowing text.rb

Text rendering can be as simple or as complex as you want.

This example covers the most basic method: text. It is meant for free flowing text. The provided string will flow according to the current bounding box width and height. It will also flow onto the next page if the bottom of the bounding box is reached.

The text will start being rendered on the current cursor position. When it finishes rendering, the cursor is left directly below the text.

This example also shows text flowing across pages following the margin box and other bounding boxes.

```
move_cursor_to 50
text "This text will flow to the next page. " * 20

y_position = cursor - 50

text/positioned_text.rb

Sometimes we want the text on a specific position on the page. The text method just won't help

There are two other methods for this task: draw_text and text_box.

draw_text is very simple. It will render text starting at the position provided to the :at option. It
won't flow to a new line even if it hits the document boundaries so it is best suited for short text.

text_box gives us much more control over the output. Just provide:width and :height options and the text will flow accordingly. Even if you don't provide a :width option the text will flow to a new line if it reaches the right border.

Given that, text_box is the better option available.

This draw text line is absolute positioned. However don't expect it to flo

This is a text box, you can control where it will flow by specifying the :height and :width options

Another text box with no :width option passed, so it will flow to a new line whenever it reaches the right margin.

text/text_box_overflow.rb

The text_box method accepts both :width and :height options. So what happens if the text doesn't fit the box?

The default behavior is to truncate the text but this can be changed with the :overflow option.

Available modes are :expand (the box will increase to fit the text) and :shrink_to_fit (the text font size will be shrunk to fit).

If :shrink_to_fit mode is used with the :min_font_size option set, the font size will not be reduced to less than the value provided even if it means truncating some text.

If the :disable_wrap_by_char is set totrue then any text wrapping done while using the :shrink to fit mode will not break up the middle of words.

This is the sample text used for the text boxes. See how it behave with the various overflow options used.

This is the sample text used for the text boxes. See

This is the sample text used for the text boxes. See how it behave with the various

overflow options

This is the sample text used for the text boxes. See how it behave with the various overflow options used.

If the box is too small for the text, :shrink_to_fit can render the text in a really small font size.

used.

text/text_box_excess.rb

Whenever the text_box method truncates text, this truncated bit is not lost, it is the method return value and we can take advantage of that.

We just need to take some precautions.

This example renders as much of the text as will fit in a larger font inside one text_box and then proceeds to render the remaining text in the default size in a second text_box.

```
string = "This is the beginning of the text. It will be cut somewhere and " +
    "the rest of the text will procede to be rendered this time by " +
    "calling another method." + " . " * 50

y_position = cursor - 20
excess_text = text_box string,
    :width => 300,
    :height => 50,
    :overflow => :truncate,
    :at => [100, y_position],
    :size => 18

text_box excess_text,
    :width => 300,
    :at => [100, y_position - 100]
```

This is the beginning of the text. It will be cut somewhere and the rest of the

 The column_box method allows you to define columns that flow their contents from one section to the next. You can have a number of columns on the page, and only when the last column overflows will a new page be created.

The Prince Niccolò Machiavelli

All the States and Governments by which men are or ever have been ruled, have been and are either Republics or Princedoms. Princedoms are either hereditary, in which the sovereignty is derived through an ancient line of ancestors, or they are new. New Princedoms are either wholly new, as that of Milan to Francesco Sforza; or they are like limbs joined on to the hereditary possessions of the Prince who acquires them, as the Kingdom of Naples to the dominions of the King of Spain. The States thus acquired have either been used to live under a Prince or have been free; and he who acquires them does so either by his own arms or by the arms of others, and either by good fortune or by merit.

text/font.rb

The font method can be used in three different ways.

If we don't pass it any arguments it will return the current font being used to render text.

If we just pass it a font name it will use that font for rendering text through the rest of the document.

It can also be used by passing a font name and a block. In this case the specified font will only be used to render text inside the block.

The default font is Helvetica.

```
text "Let's see which font we are using: #{font.inspect}"

move_down 20
font "Times-Roman"
text "Written in Times."

move_down 20
font("Courier") do
    text "Written in Courier because we are inside the block."
end

move_down 20
text "Written in Times again as we left the previous block."

move_down 20
text "Let's see which font we are using again: #{font.inspect}"

move_down 20
font "Helvetica"
text "Back to normal."
```

Let's see which font we are using: Prawn::Font::AFM< Helvetica: 12 >

Written in Times.

Written in Courier because we are inside the block.

Written in Times again as we left the previous block.

Let's see which font we are using again: Prawn::Font::AFM< Times-Roman: 12 >

Back to normal.

text/font_size.rb

The font_size method works just like the font method.

In fact we can even use font with the :size option to declare which size we want.

Another way to change the font size is by supplying the : size option to the text methods.

The default font size is 12.

```
text "Let's see which is the current font_size: #{font_size.inspect}"

move_down 10
font_size 16
text "Yeah, something bigger!"

move_down 10
font_size(25) { text "Even bigger!" }

move_down 10
text "Back to 16 again."

move_down 10
text "Single line on 20 using the :size option.", :size => 20

move_down 10
text "Back to 16 once more."

move_down 10
font("Courier", :size => 10) do
    text "Yeah, using Courier 10 courtesy of the font method."
end

move_down 10
font("Helvetica", :size => 12)
text "Back to normal"
```

Let's see which is the current font size: 12

Yeah, something bigger!

Even bigger!

Back to 16 again.

Single line on 20 using the :size option.

Back to 16 once more.

Yeah, using Courier 10 courtesy of the font method.

Back to normal

text/font_style.rb

Most font families come with some styles other than normal. Most common are **bold**, **italic** and **bold_italic**.

The style can be set the using the :style option, with either the font method which will set the font and style for rest of the document, or with the inline text methods.

```
["Courier", "Helvetica", "Times-Roman"].each do |example_font|
  move_down 20

[:bold, :bold_italic, :italic, :normal].each do |style|
  font example_font, :style => style
   text "I'm writing in #{example_font} (#{style})"
  end
end
```

I'm writing in Courier (bold)
I'm writing in Courier (bold_italic)
I'm writing in Courier (italic)

I'm writing in Courier (normal)

I'm writing in Helvetica (bold)
I'm writing in Helvetica (bold_italic)

I'm writing in Helvetica (italic) I'm writing in Helvetica (normal)

I'm writing in Times-Roman (bold)
I'm writing in Times-Roman (bold_italic)

*I'm writing in Times-Roman (italic)*I'm writing in Times-Roman (normal)

text/color.rb

The :color attribute can give a block of text a default color, in RGB hex format or 4-value CMYK.

Default color is black

Changed to red

CMYK color

Also works with inline formatting

text/alignment.rb

Horizontal text alignment can be achieved by supplying the :align option to the text methods. Available options are :left (default), :right, :center, and :justify.

Vertical text alignment can be achieved using the :valign option with the text methods. Available options are :top (default), :center, and :bottom.

Both forms of alignment will be evaluated in the context of the current bounding_box.

This text should be left aligned

This text should be centered

This text should be right aligned

This text is flowing from the left. This text is flowing from the left. This text is flowing from the left. This text is flowing from the left.

This text is flowing from the center. This text is flowing from the center. This text is flowing from the center.

This text is flowing from the right. This text is flowing from the right. This text is flowing from the right. This text is flowing from the right.

This text is justified. This text is justified.

This text should be vertically top aligned

This text should be vertically centered

This text should be vertically bottom aligned

text/leading.rb

Leading is the additional space between lines of text.

The leading can be set using the default_leading method which applies to the rest of the document or until it is changed, or inline in the text methods with the :leading option.

The default leading is 0.

```
string = "Hey, what did you do with the space between my lines? " * 10
text string, :leading => 0

move_down 20
default_leading 5
text string

move_down 20
text string, :leading => 10
```

Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines?

Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines?

Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines? Hey, what did you do with the space between my lines?

text/kerning and character spacing.rb

Kerning is the process of adjusting the spacing between characters in a proportional font. It is usually done with specific letter pairs. We can switch it on and off if it is available with the current font. Just pass a boolean value to the :kerning option of the text methods.

Character Spacing is the space between characters. It can be increased or decreased and will have effect on the whole text. Just pass a number to the :character_spacing option from the text methods.

```
font_size(30) do
  text_box "With kerning:", :kerning => true, :at => [0, y - 40]
  text_box "Without kerning:", :kerning => false, :at => [0, y - 80]

text_box "Tomato", :kerning => true, :at => [250, y - 40]
  text_box "Tomato", :kerning => false, :at => [250, y - 80]

text_box "WAR", :kerning => true, :at => [400, y - 40]
  text_box "WAR", :kerning => false, :at => [400, y - 80]

text_box "F.", :kerning => true, :at => [500, y - 40]
  text_box "F.", :kerning => false, :at => [500, y - 80]

end

move_down 80

string = "What have you done to the space between the characters?"
[-2, -1, 0, 0.5, 1, 2].each do [spacing]
  move_down 20
  text "#{string} (character_spacing: #{spacing})",
    :character_spacing => spacing
end
```

With kerning: Tomato WAR F. Without kerning: Tomato WAR F.

What have you done to the space between the characters? (character spacing: -2)

What have you done to the space between the characters? (character_spacing: -1)

What have you done to the space between the characters? (character_spacing: 0)

What have you done to the space between the characters? (character spacing: 0.5)

What have you done to the space between the characters? (character_spacing: 1)

What have you done to the space between the characters? (character_spacing: 2)

text/paragraph indentation.rb

Prawn strips all whitespace from the beginning and the end of strings so there are two ways to indent paragraphs:

One is to use non-breaking spaces which Prawn won't strip. One shortcut to using them is the Prawn::Text::NBSP.

The other is to use the :indent_paragraphs option with the text methods. Just pass a number with the space to indent the first line in each paragraph.

This paragraph won't be indented. This paragraph won't be indented.

This one will with NBSP. This one will with NBSP.

This paragraph will be indented. This paragraph will be indented.

This one will too. This one will too.

FROM RIGHT TO LEFT:

eb lliw hpargarap sihT .detnedni .detnedni eb lliw hpargarap sihT .detnedni .detnedni eb lliw hpargarap sihT .detnedni

.oot lliw eno sihT .oot lliw eno

text/rotation.rb

Rotating text is best avoided on free flowing text, so this example will only use **tlext_box** method as we can have much more control over its output.

To rotate text all we need to do is use the :rotate option passing an angle in degrees and an optional :rotate_around to indicate the origin of the rotation (the default is :upper_left).

This text was not rotated

This text was not the rotated around the rotated around left comer.

This text was not the rotated around the upper left corner.

rhis text was rotated around the rotater center

This text was nound the rotated around to rotated around to rotated around the rotated ar

This text was around the rotated around the upper right

text/inline.rb

Inline formatting gives you the option to format specific portions of a text. It uses HTML-esque syntax inside the text string. Supported tags are: **b** (bold), **i** (italic), **u** (underline), **strikethrough**, **sub** (subscript), **sup** (superscript)

The following tags accept specific attributes: font accepts size, name, and character_spacing; color accepts rgb and cmyk; link accepts href for external links.

Just your regular text **except this portion** is using the b tag

Just your regular text except this portions using the i tag

Just your regular text except this portion is using the u tag

Just your regular text except this portion is using the strikethrough tag

Just your regular text except this portion is using the sub tag

Just your regular text except this portion is using the sup tag

This $\overline{\text{line}}$ uses all the font tag attributes in a $\sin g \log \sin g$.

Coloring in both RGB and CMYK

This an external link to the Prawn wiki

text/formatted text.rb

There are two other text methods available: formatted_text and formatted_text_box.

These are useful when the provided text has numerous portions that need to be formatted differently. As you might imply from their names the first should be used for free flowing text just like the text method and the last should be used for positioned text just like text_box.

The main difference between these methods and the <code>text</code> and <code>text_box</code> methods is how the text is provided. The <code>formatted_text</code> and <code>formatted_text_box</code> methods accept an array of hashes. Each hash must provide a: <code>text</code> option which is the text string and may provide the following options: <code>:styles</code> (an array of symbols), <code>:size</code> (the font size), <code>:character_spacing</code> (additional space between the characters), <code>:font</code> (the name of a registered font), <code>:color</code> (the same input accepted by <code>fill_color</code> and <code>stroke_color</code>), <code>:link</code> (an URL to create a link), and <code>:local</code> (a link to a local file).

Some bold. Some italic. Bold ital Bigger Text. More spacing. Different Font. Some coloring. Link to the wiki. Link to a local file.

Just your regular text_box with some additional formatting options added to the mix.

The :callback option is also available for the formatted text methods.

This option accepts an object (or array of objects) on which two methods will be called if defined: render_behind and render_in_front. They are called before and after rendering the text fragment and are passed the fragment as an argument.

This example defines two new callback classes and provide callback objects for the formatted text

```
class HighlightCallback
  def initialize(options)
  def render_behind(fragment)
   original_color = @document.fill_color
    @document.fill_color = @color
                             fragment.width,
                             fragment.height)
    @document.fill_color = original_color
class ConnectedBorderCallback
 def initialize (options)
   @radius = options[:radius]
   @document = options[:document]
  def render_in_front(fragment)
   @document.stroke_polygon(fragment.top_left, fragment.top_right,
                             fragment.bottom_right, fragment.bottom_left)
    @document.fill_circle(fragment.top_left,
    @document.fill_circle(fragment.top_right,
    @document.fill_circle(fragment.bottom_right, @radius)
    @document.fill_circle(fragment.bottom_left, @radius)
  end
highlight = HighlightCallback.new(:color => 'fffff00', :document => self)
formatted_text [ { :text => "hello", :callback => highlight },
                 { :text => "hello world", :callback => [highlight, border] }
```

text/rendering_and_color.rb

You have already seen how to set the text color using both inline formatting and the format text methods. There is another way by using the graphics methodsfill_color and stroke_color.

When reading the graphics reference you learned about fill and stroke. If you haven't read it before, read it now before continuing.

Text can be rendered by being filled (the default mode) or just stroked or both filled and stroked. This can be set using the text_rendering_mode method or the :mode option on the text methods.

```
fill_color "000ff00"
stroke_color "0000ff"

font_size(40) do
    # normal rendering mode: fill
    text "This text is filled with green."
    move_down 20

# inline rendering mode: stroke
    text "This text is stroked with blue", :mode => :stroke
    move_down 20

# block rendering mode: fill and stroke
    text_rendering_mode(:fill_stroke) do
        text "This text is filled with green and stroked with blue"
    end
end
```

This text is filled with green.

This text is stroked with blue

This text is filled with green and stroked with blue

text/text_box_extensions.rb

We've already seen one way of using text boxes with the text_box method. Turns out this method is just a convenience for using the Prawn::Text::Box class as it creates a new object and call render on it.

Knowing that any extensions we add to take effect when we use the text_box method. To add an extension all we need to do is append the Prawn::Text::Box.extensions array with a module.

```
module TriangleBox
  def available_width
   height + 25
y_{position} = cursor - 10
\begin{array}{ll} \text{width} & = 100 \\ \text{height} & = 100 \end{array}
Prawn::Text::Box.extensions << TriangleBox</pre>
stroke_rectangle([0, y_position], width, height)
text_box("A" * 100,
          :at => [0, y_position],
          :width => width,
          :height => height)
Prawn::Text::Formatted::Box.extensions << TriangleBox</pre>
stroke\_rectangle([200, y\_position], width, height)
formatted_text_box([:text => "A" * 100, :color => "009900"],
                      :at => [200, y_position],
                      :height => height)
```

text/single_usage.rb

The PDF format has some built-in font support. If you want to use other fonts in Prawn you need to embed the font file.

Doing this for a single font is extremely simple. Remember the Styling font example? Another use of the font method is to provide a font file path and the font will be embedded in the document and set as the current font.

This is reasonable if a font is used only once, but, if a font used several times, providing the path each time it is used becomes cumbersome. The example on the next page shows a better way to deal with fonts which are used several times in a document.

```
# Using a TTF font file
font("#{Prawn::DATADIR}/fonts/DejaVuSans.ttf") do
    text "Written with the DejaVu Sans TTF font."
end
move_down 20

text "Written with the default font."
move_down 20

# Using an DFONT font file
font("#{Prawn::DATADIR}/fonts/Panic+Sans.dfont") do
    text "Written with the Panic Sans DFONT font"
end
move_down 20

text "Written with the default font once more."
```

Written with the DejaVu Sans TTF font.

Written with the default font.

Written with the Panic Sans DFONT font

Written with the default font once more.

text/registering_families.rb

Registering font families will help you when you want to use a font over and over or if you would like to take advantage of the <code>:style</code> option of the text methods and the <code>b</code> and <code>i</code> tags when using inline formatting.

To register a font family update the **font_families** hash with the font path for each style you want to use.

Using the DejaVu Sans font providing only its name to the font method

Also using Panic Sans by providing only its name

Taking **advantage** of the *inline formatting*

Using the bold style option.

Using the bold_italic style option.

Using the italic style option.

Using the normal style option.

Multilingualization isn't much of a problem on Prawn as its default encoding is UTF-8. The only thing you need to worry about is if the font support the glyphs of your language.

Take this example, a simple Euro sign:

This works, because € is one of the few non-ASCII glyphs supported in PDF built-in fonts.

For full internationalized text support, we need to use TTF fonts:

ὕαλον φαγεῖν δύναμαι· τοῦτο οὔ με βλάπτει. There you go.

text/line wrapping.rb

Line wrapping happens on white space or hyphens. Soft hyphens can be used to indicate where words can be hyphenated. Non-breaking spaces can be used to display space without allowing for a break.

For writing styles that do not make use of spaces, the zero width space serves to mark word boundaries. Zero width spaces are available only with TTF fonts.

```
move_down 20
move_down 20
nbsp = Prawn::Text::NBSP
    "Slip#{nbsp}sliding away, slip#{nbsp}sliding awaaaay. You know the " +
move down 20
font("#{Prawn::DATADIR}/fonts/gkai00mp.ttf", :size => 16) do

text/right_to_left_text.rb

Prawn can be used with right-to-left text. The direction can be set document-wide, on particular text, or on a text-box. Setting the direction to :rtl automatically changes the default alignment to :right

You can even override direction on an individual fragment. The one caveat is that two fragments going against the main direction cannot be placed next to each other without appearing in the wrong order.

Writing bidirectional text that combines both left-to-right and right-to-left languages is easy using the bidi Ruby Gem and its render_visual function. See https://github.com/elad/ruby-bidi for instructions and an example using Prawn.

text/fallback_fonts.rb

Prawn enables the declaration of fallback fonts for those glyphs that may not be present in the desired font. Use the <code>:fallback_fonts</code> option with any of the text or text box methods, or set fallback_fonts document-wide.

```
file = "#{Prawn::DATADIR}/fonts/gkai00mp.ttf"
font_families["Kai"] = {
    :normal => { :file => file, :font => "Kai" }
}

file = "#{Prawn::DATADIR}/fonts/Panic+Sans.dfont"
font_families["Panic Sans"] = {
    :normal => { :file => file, :font => "PanicSans" }
}

font("Panic Sans") do
    text("When fallback fonts are included, each glyph will be rendered " +
        "using the first font that includes the glyph, starting with the " +
        "current font and then moving through the fallback fonts from left " +
        "to right." +
        "\n\n" +
        "hello f forf\n\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\mathra{\m
```

When fallback fonts are included, each glyph will be rendered using the first font that includes the glyph, starting with the current font and then moving through the fallback fonts from left to right.

hello f 你好 再见 f goodbye

Fallback fonts can even overrideragment fonts (你好)

Prints a list of all of the glyphs that can be rendered by Adobe's built in fonts, along with their character widths and WinAnsi codes. Be sure to pass these glyphs as UTF-8, and Prawn will transcode them for you.

```
move_down 30
start_new_page
Prawn::Encoding::WinAnsi::CHARACTERS.each_with_index do |name, index|
  y -= FONT_SIZE
  if y < FONT_SIZE
   y = bounds.top - FONT_SIZE
  width = 1000 * width_of(char, :size => FONT_SIZE) / FONT_SIZE
     width = width_of(field, :size => FONT_SIZE)
     case align
     when :left
                  then offset = 0
     when :center then offset = (total_width - width) / 2
     text_box(field.force_encoding("windows-1252").encode("UTF-8"),
               :at \Rightarrow [dx + offset, y])
```

Bounding box

Bounding boxes are the basic containers for structuring the content flow. Even being low level building blocks sometimes their simplicity is very welcome.

The examples show:

- How to create bounding boxes with specific dimensions
- How to inspect the current bounding box for its coordinates
- Stretchy bounding boxes
- Nested bounding boxes
- · Indent blocks

bounding_box/creation.rb

If you've read the basic concepts examples you probably know that the origin of a page is on the bottom left corner and that the content flows from top to bottom.

You also know that a Bounding Box is a structure for helping the content flow.

A bounding box can be created with the **bounding_box** method. Just provide the top left corner, a required :width option and an optional :height.

```
bounding_box([200, cursor - 100], :width => 200, :height => 100) do
  text "Just your regular bounding box"

  transparent(0.5) { stroke_bounds }
end
```

_

bounding_box/bounds.rb

The **bounds** method returns the current bounding box. This is useful because the **Prawn::BoundingBox** exposes some nice boundary helpers.

top, bottom, left and right methods return the bounding box boundaries relative to its translated origin. top_left, top_right, bottom_left and bottom_right return those boundaries pairs inside arrays.

All these methods have an "absolute" version like absolute_right. The absolute version returns the same boundary relative to the page absolute coordinates.

The following snippet shows the boundaries for the margin box side by side with the boundaries for a custom bounding box.

```
def print_coordinates
  text "top: #{bounds.top}"
  text "bottom: #{bounds.bottom}"
  text "leff: #{bounds.left}"
  text "right: #{bounds.right}"

move_down 10

text "absolute top: #{sprintf "%.2f", bounds.absolute_top}"
  text "absolute bottom: #{sprintf "%.2f", bounds.absolute_bottom}"
  text "absolute left: #{sprintf "%.2f", bounds.absolute_left}"
  text "absolute right: #{sprintf "%.2f", bounds.absolute_right}"
  end

text "Margin box bounds:"
  move_down 5
  print_coordinates

bounding_box([250, cursor + 140], :width => 200, :height => 150) do
  text "This bounding box bounds:"
  move_down 5
  print_coordinates
  transparent(0.5) { stroke_bounds }
  end
```

Margin box bounds:

top: 864.0 bottom: 0 left: 0 right: 540.0

absolute top: 900.00 absolute bottom: 36.00 absolute left: 36.00 absolute right: 576.00 This bounding box bounds:

top: 150 bottom: 0 left: 0 right: 200

absolute top: 263.17 absolute bottom: 113.17 absolute left: 286.00 absolute right: 486.00

bounding_box/stretchy.rb

Bounding Boxes accept an optional :height parameter. Unless it is provided the bounding box will be stretchy. It will expand the height to fit all content generated inside it.

This bounding box has a height of 100. If this text gets too large it will flow to the next page.

bounding_box/nesting.rb

Normally when we provide the top left corner of a bounding box we express the coordinates relative to the margin box. This is not the case when we have nested bounding boxes. Once nested the inner bounding box coordinates are relative to the outter bounding box.

This example shows some nested bounding boxes with fixed and stretchy heights. Note how the cursor method returns coordinates relative to the current bounding box.

```
def box_content(string)
  text string
  transparent(0.5) { stroke_bounds }
end

gap = 20
bounding_box([50, cursor], :width => 400, :height => 200) do
  box_content("Fixed height")

bounding_box([gap, cursor - gap], :width => 300) do
  text "Stretchy height"

  bounding_box([gap, bounds.top - gap], :width => 100) do
    text "Stretchy height"
    transparent(0.5) { dash(1); stroke_bounds; undash }
  end

  bounding_box([gap * 7, bounds.top - gap], :width => 100, :height => 50) do
    box_content("Fixed height")
  end

  bounding_box([gap, cursor - gap], :width => 300, :height => 50) do
    box_content("Fixed height")
  end
end
```

Fixe	ed height		
	Stretchy height		
	Stretchy height	Fixed height	
	······		
	Fixed height		7
	Fixed height		
			1

bounding_box/indentation.rb

Sometimes you just need to indent a portion of the contents of a bounding box, and using a nested bounding box is pure overkill. The **indent** method is what you might need.

Just provide a number for it to indent all content generated inside the block.

No indentation on the margin box.

Some indentation inside an indent block.

No indentation inside this bounding box.
Inside an indent block. And so is this horizontal line:

No indentation

Another indent block.

Note that this bounding box coordinates are relative to the indent block

bounding_box/canvas.rb

The origin example already mentions that a new document already comes with a margin box whose bottom left corner is used as the origin for calculating coordinates.

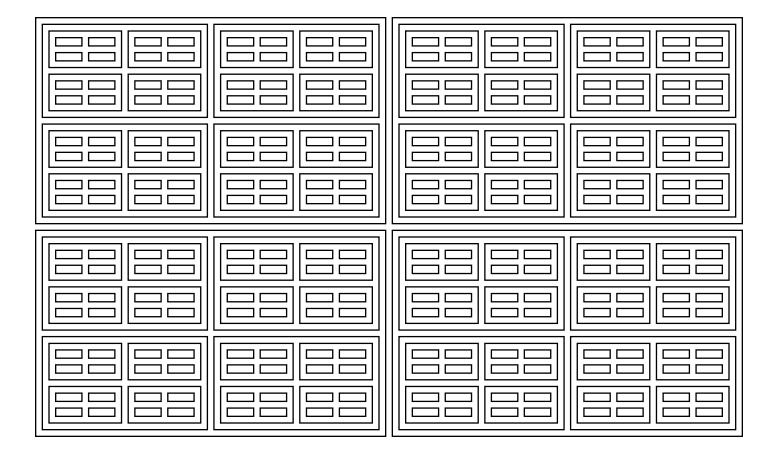

What has not been told is that there is one helper for "bypassing" the margin box: canvas. This method is a shortcut for creating a bounding box mapped to the absolute coordinates and evaluating the code inside it.

The following snippet draws a circle on each of the four absolute corners.

```
canvas do
  fill_circle [bounds.left, bounds.top], 30
  fill_circle [bounds.right, bounds.top], 30
  fill_circle [bounds.right, bounds.bottom], 30
  fill_circle [0, 0], 30
end
```

bounding_box/russian_boxes.rb

This example is mostly just for fun, and shows how nested bounding boxes can simplify calculations. See the "Bounding Box" section of the manual for more basic uses.

Layout

Prawn has support for two-dimensional grid based layouts out of the box.

The examples show:

- · How to define the document grid
- How to configure the grid rows and columns gutters
- · How to create boxes according to the grid

layout/simple_grid.rb

The document grid on Prawn is just a table-like structure with a defined number of rows and columns. There are some helpers to create boxes of content based on the grid coordinates.

define_grid accepts the following options which are pretty much self-explanatory: :rows,
:columns, :gutter, :row_gutter, :column_gutter

```
# The grid only need to be defined once, but since all the examples should be
# able to run alone we are repeating it on every example
define_grid(:columns => 5, :rows => 8, :gutter => 10)
text "We defined the grid, roll over to the next page to see its outline"
start_new_page
grid.show_all
```

We defined the grid, roll over to the next page to see its outline

0,0	0,1	0,2	0,3	0,4	
1,0	1,1	1,2	1,3	1,4	
2,0	2,1	2,2	2,3	2,4	
3,0	3,1	3,2	3,3	3,4	
4,0	4,1	4,2	4,3	4,4	
5,0	5,1	5,2	5,3	5,4	
6,0	6,1	6,2	6,3	6,4	
7,0	7,1	7,2	7,3	7,4	

layout/boxes.rb

After defined the grid is there but nothing happens. To start taking effect we need to use the grid boxes.

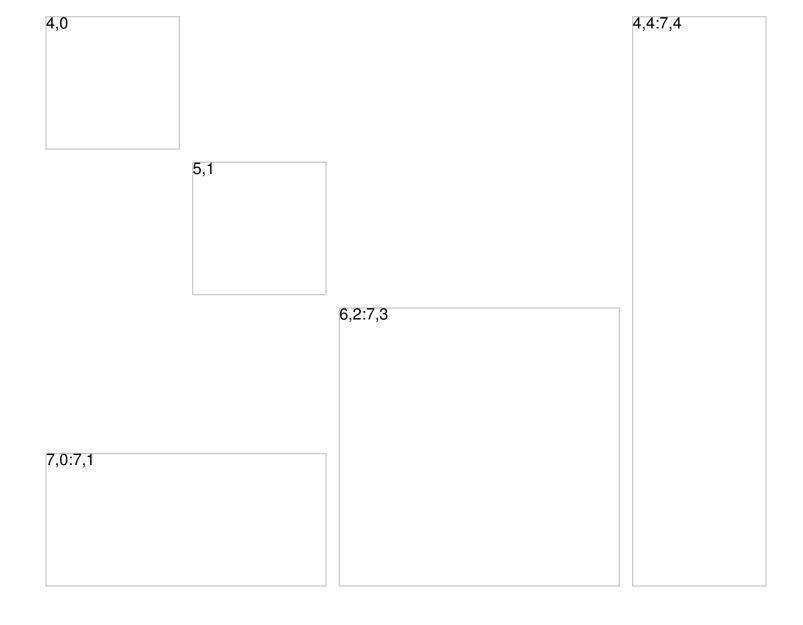

grid has three different return values based on the arguments received. With no arguments it will return the grid itself. With integers it will return the grid box at those indices. With two arrays it will return a multi-box spanning the region of the two grid boxes at the arrays indices.

```
# The grid only need to be defined once, but since all the examples should be
# able to run alone we are repeating it on every example
define_grid(:columns => 5, :rows => 8, :gutter => 10)

grid(4, 0).show
grid(5, 1).show

grid([6, 2], [7, 3]).show

grid([4, 4], [7, 4]).show
grid([7, 0], [7, 1]).show
```

layout/content.rb

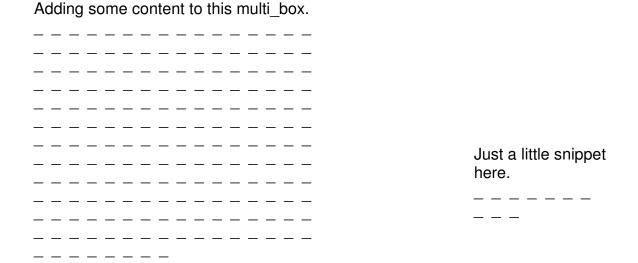

Now that we know how to access the boxes we might as well add some content to them.

This can be done by taping into the bounding box for a given grid box or multi-box with the bounding_box method.

```
# The grid only need to be defined once, but since all the examples should be
# able to run alone we are repeating it on every example
define_grid(:columns => 5, :rows => 8, :gutter => 10)

grid([5, 0], [7, 1]).bounding_box do
   text "Adding some content to this multi_box.\n" + " _ " * 200
end

grid(6, 3).bounding_box do
   text "Just a little snippet here.\n" + " _ " * 10
end
```

Prawn::Table

As of Prawn 1.2.0, Prawn::Table has been extracted into its own semi-officially supported gem.

Please see https://github.com/prawnpdf/prawn-table for more details.

Images

Embedding images on PDF documents is fairly easy. Prawn supports both JPG and PNG images.

The examples show:

- How to add an image to a page
- How place the image on a specific position
- How to configure the image dimensions by setting the width and height or by scaling it

images/plain_image.rb

To embed images onto your PDF file use the image method. It accepts the file path of the image to be loaded and some optional arguments.

If only the image path is provided the image will be rendered starting on the cursor position. No manipulation is done with the image even if it doesn't fit entirely on the page like the following snippet.

text "The image will go right below this line of text."
image "#{Prawn::DATADIR}/images/pigs.jpg"

The image will go right below this line of text.

images/absolute_position.rb

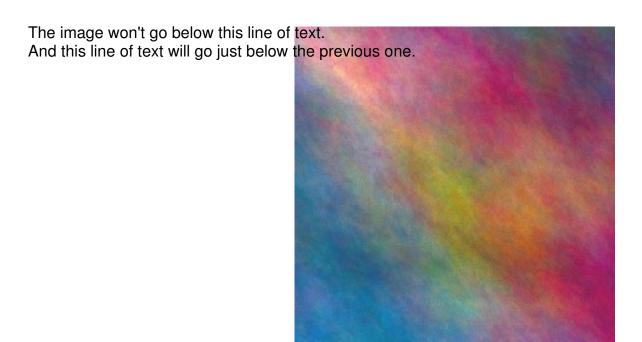

One of the options that the <code>image</code> method accepts is <code>:at</code>. If you've read some of the graphics examples you are probably already familiar with it. Just provide it the upper-left corner where you want the image placed.

While sometimes useful this option won't be practical. Notice that the cursor won't be moved after the image is rendered and there is nothing forbidding the text to overlap with the image.

```
y_position = cursor
text "The image won't go below this line of text."

image "#{Prawn::DATADIR}/images/fractal.jpg", :at => [200, y_position]

text "And this line of text will go just below the previous one."
```

images/horizontal.rb

The image may be positioned relatively to the current bounding box. The horizontal position may be set with the :position option.

It may be :left, :center, :right or a number representing an x-offset from the left boundary.

```
bounding_box([50, cursor], :width => 400, :height => 450) do
   stroke_bounds

[:left, :center, :right].each do |position|
   text "Image aligned to the #{position}."
   image "#{Prawn::DATADIR}/images/stef.jpg", :position => position
   end

text "The next image has a 50 point offset from the left boundary"
   image "#{Prawn::DATADIR}/images/stef.jpg", :position => 50
end
```

Image aligned to the left.

Image aligned to the center.

Image aligned to the right.

The next image has a 50 point offset from the left boundary

images/vertical.rb

To set the vertical position of an image use the :vposition option.

It may be :top, :center, :bottom or a number representing the y-offset from the top boundary.

Image vertically aligned to the top.

The next image has a 100 point offset from the top boundary

Image vertically aligned to the center.

Image vertically aligned to the bottom.

images/width_and_height.rb

The image size can be set with the :width and :height options.

If only one of those is provided, the image will be scaled proportionally. When both are provided, the image will be stretched to fit the dimensions without maintaining the aspect ratio.

```
text "Scale by setting only the width"
image "#{Prawn::DATADIR}/images/pigs.jpg", :width => 150
move_down 20

text "Scale by setting only the height"
image "#{Prawn::DATADIR}/images/pigs.jpg", :height => 100
move_down 20

text "Stretch to fit the width and height provided"
image "#{Prawn::DATADIR}/images/pigs.jpg", :width => 500, :height => 100
```

Scale by setting only the width

Scale by setting only the height

Stretch to fit the width and height provided

images/scale.rb

To scale an image use the :scale option.

It scales the image proportionally given the provided value.

```
text "Normal size"
image "#{Prawn::DATADIR}/images/stef.jpg"
move_down 20

text "Scaled to 50%"
image "#{Prawn::DATADIR}/images/stef.jpg", :scale => 0.5
move_down 20

text "Scaled to 200%"
image "#{Prawn::DATADIR}/images/stef.jpg", :scale => 2
```

Normal size

Scaled to 50%

Scaled to 200%

images/fit.rb

:fit option is useful when you want the image to have the maximum size within a container preserving the aspect ratio without overlapping.

Just provide the container width and height pair.

```
size = 300

text "Using the fit option"
bounding_box([0, cursor], :width => size, :height => size) do
   image "#{Prawn::DATADIR}/images/pigs.jpg", :fit => [size, size]
   stroke_bounds
end
```

Using the fit option

Document and page options

So far we've already seen how to create new documents and start new pages. This chapter expands on the previous examples by showing other options avialable. Some of the options are only available when creating new documents.

The examples show:

- · How to configure page size
- How to configure page margins
- · How to use a background image
- · How to add metadata to the generated PDF

document_and_page_options/page_size.rb

Prawn comes with support for most of the common page sizes so you'll only need to provide specific values if your intended format is not supported. To see a list with all supported sizes take a look at PDF::Core::PageGeometry

To define the size use :page_size when creating new documents and :size when starting new pages. The default page size for new documents is LETTER (612.00 x 792.00).

You may also define the orientation of the page to be either portrait (default) or landscape. Use :page_layout when creating new documents and :layout when starting new pages.

This code snippet was not evaluated inline. You may see its output by running the example file located here: http://github.com/prawnpdf/prawn/tree/master/manual/document_and_page_options/page_size.rb

document_and_page_options/page_margins.rb

The default margin for pages is 0.5 inch but you can change that with the :margin option or if you'd like to have different margins you can use the :left_margin, :right_margin, :top_margin, :bottom_margin options.

These options are available both for starting new pages and creating new documents.

This code snippet was not evaluated inline. You may see its output by running the example file located here: http://github.com/prawnpdf/prawn/tree/master/manual/document_and_page_options/page_margins.rb

document_and_page_options/background.rb

Pass an image path to the:background option and it will be used as the background for all pages. This option can only be used on document creation.

This code snippet was not evaluated inline. You may see its output by running the example file located here: http://github.com/prawnpdf/prawn/tree/master/manual/document_and_page_options/background.rb

document_and_page_options/metadata.rb

To set the document metadata just pass a hash to the :info option when creating new documents. The keys in the example below are arbitrary, so you may add whatever keys you want

This code snippet was not evaluated inline. You may see its output by running the example file located here: http://github.com/prawnpdf/prawn/tree/master/manual/document_and_page_options/metadata.rb

document_and_page_options/print_scaling.rb

(Optional; PDF 1.6) The page scaling option to be selected when a print dialog is displayed for this document. Valid values are None, which indicates that the print dialog should reflect no page scaling, and AppDefault, which indicates that applications should use the current print scaling. If this entry has an unrecognized value, applications should use the current print scaling. Default value: AppDefault.

Note: If the print dialog is suppressed and its parameters are provided directly by the application, the value of this entry should still be used.

This code snippet was not evaluated inline. You may see its output by running the example file located here: http://github.com/prawnpdf/prawn/tree/master/manual/document and page options/print scaling.rb

Outline

The outline of a PDF document is the table of contents tab you see to the right or left of your PDF viewer.

The examples include:

- How to define sections and pages
- How to insert sections and/or pages to a previously defined outline structure

outline/sections_and_pages.rb

The document outline tree is the set of links used to navigate through the various document sections and pages.

To define the document outline we first use the **outline** method to lazily instantiate an outline object. Then we use the **define** method with a block to start the outline tree.

The basic methods for creating outline nodes are section and page. The only difference between the two is that page doesn't accept a block and will only create leaf nodes while section accepts a block to create nested nodes.

section accepts the title of the section and two options: :destination - a page number to link and :closed - a boolean value that defines if the nested outline nodes are shown when the document is open (defaults to true).

page is very similar to section. It requires a :title option to be set and accepts a
:destination.

section and page may also be used without the define method but they will need to instantiate the outline object every time.

```
# First we create 10 pages just to have something to link to
(1..10).each do |index|
    text "Page #{index}"
    start_new_page
end

outline.define do
    section("Section 1", :destination => 1) do
    page :title => "Page 2", :destination => 2
    page :title => "Page 3", :destination => 3
    end

section("Section 2", :destination => 4) do
    page :title => "Page 5", :destination => 5

    section("Subsection 2.1", :destination => 6, :closed => true) do
        page :title => "Page 7", :destination => 7
    end
    end
end

# Outside of the define block
outline.section("Section 3", :destination => 8) do
    outline.page :title => "Page 9", :destination => 9
end

outline.page :title => "Page 10", :destination => 10

# Section and Pages without links. While a section without a link may be
# useful to group some pages, a page without a link is useless
outline.update do # update is an alias to define
    section("Section without link") do
    page :title => "Page without link" do
    page :title => "Page without link"
end
```

outline/add_subsection_to.rb

We have already seen how to define an outline tree sequentially.

If you'd like to add nodes to the middle of an outline tree the add_subsection_to may help you.

It allows you to insert sections to the outline tree at any point. Just provide the title of the parent section, the position you want the new subsection to be inserted :first or :last (defaults to :last) and a block to declare the subsection.

The add_subsection_to block doesn't necessarily create new sections, it may also create new pages.

If the parent title provided is the title of a page. The page will be converted into a section to receive the subsection created.

This code snippet was not evaluated inline. You may see its output by running the example file located here: http://github.com/prawnpdf/prawn/tree/master/manual/outline/add_subsection_to.rb

outline/insert_section_after.rb

Another way to insert nodes into an existing outline is the insert_section_after method.

It accepts the title of the node that the new section will go after and a block declaring the new section.

As is the case with add_subsection_to the section added doesn't need to be a section, it may be just a page.

```
# First we create 10 pages and some default outline
(1..10).each do |index|
    text "Page #(index)"
    start_new_page
end

outline.define do
    section("Section 1", :destination => 1) do
        page :title => "Page 2", :destination => 2
        page :title => "Page 3", :destination => 3
        end
end

# Now we will start adding nodes to the previous outline
outline.insert_section_after("Page 2") do
        outline.section("Section after Page 2") do
        outline.page :title => "Page 4", :destination => 4
        end
end

outline.insert_section_after("Section 1") do
        outline.section("Section after Section 1") do
        outline.page :title => "Page 5", :destination => 5
        end
end

# Adding just a page
outline.insert_section_after("Page 3") do
        outline.page :title => "Page after Page 3", :destination => 6
end
```

This code snippet was not evaluated inline. You may see its output by running the example file located here: http://github.com/prawnpdf/prawn/tree/master/manual/outline/insert_section_after.rb

Repeatable content

Prawn offers two ways to handle repeatable content blocks. Repeater is useful for content that gets repeated at well defined intervals while Stamp is more appropriate if you need better control of when to repeat it.

There is also one very specific helper for numbering pages.

The examples show:

- How to repeat content on several pages with a single invocation
- · How to create a new Stamp
- How to "stamp" the content block on the page
- · How to number the document pages with one simple call
